

## Sorting means . . .

- The values stored in an array have keys of a type for which the relational operators are defined. (We also assume unique keys.)
- Sorting rearranges the elements into either ascending or descending order within the array. (We'll use ascending order.)

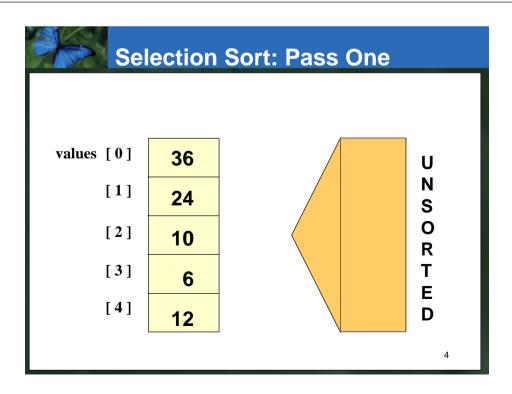

2

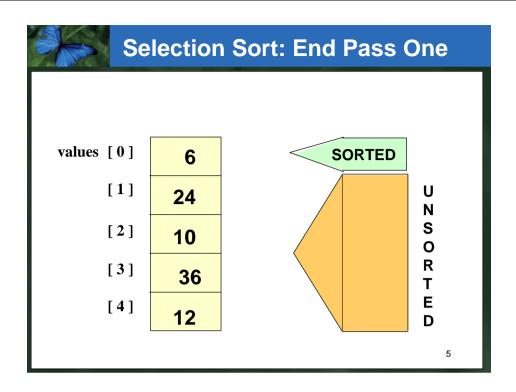

## **Straight Selection Sort**

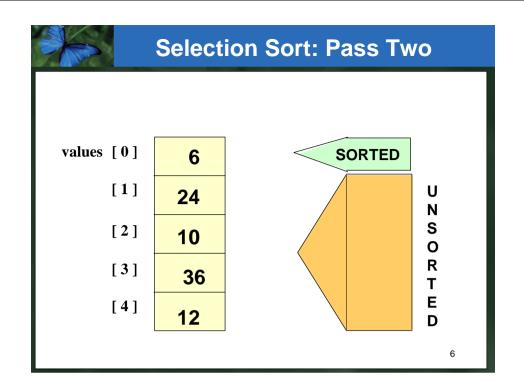

values [0]	36
[1]	24
[2]	10
[3]	6
[4]	12

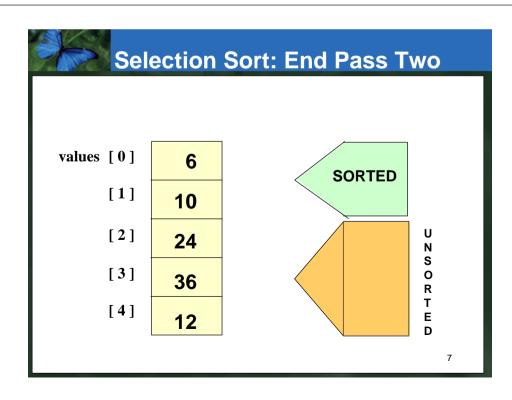

Divides the array into two parts: already sorted, and not yet sorted.

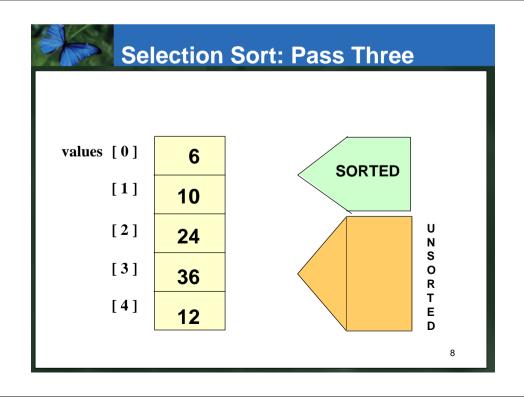

On each pass, finds the smallest of the unsorted elements, and swaps it into its correct place, thereby increasing the number of sorted elements by one.

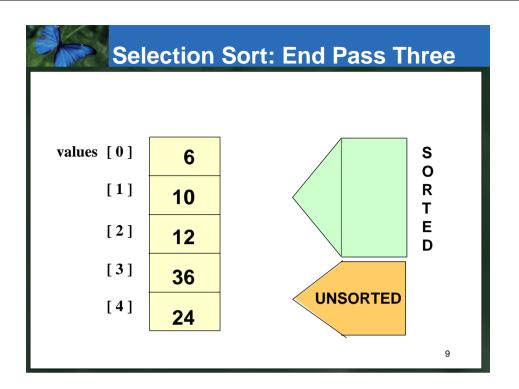

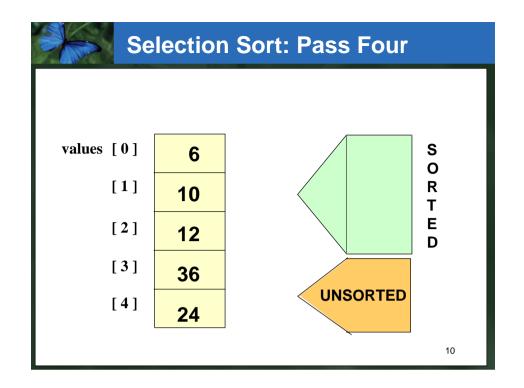

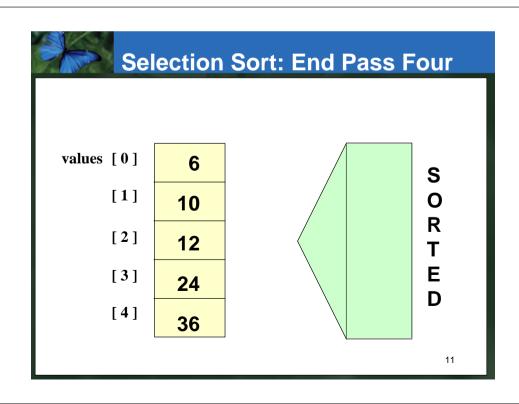

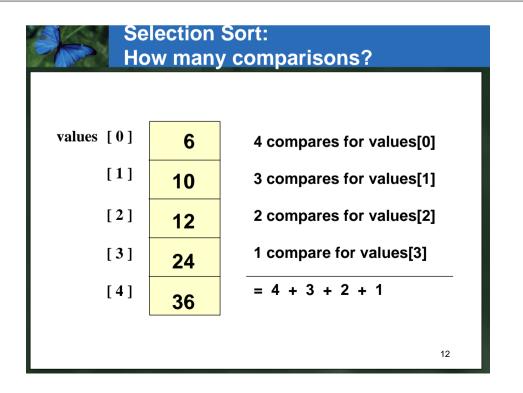

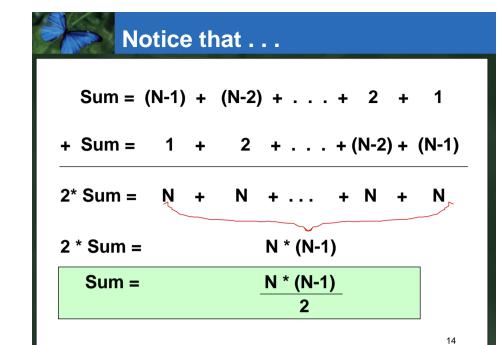

## For selection sort in general

 The number of comparisons when the array contains N elements is

$$Sum = (N-1) + (N-2) + ... + 2 + 1$$

13

## For selection sort in general

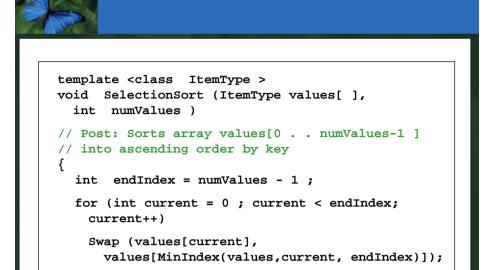

The number of comparisons when the array contains N elements is

```
template <class ItemType >
int MinIndex(ItemType values [ ], int start, int end)
// Post: Function value = index of the smallest value
// in values [start] . . values [end].
{
  int indexOfMin = start ;

  for(int index = start + 1 ; index <= end ; index++)
    if (values[ index] < values [indexOfMin])
        indexOfMin = index ;

  return indexOfMin;
}</pre>
```

17

## Bubble Sort

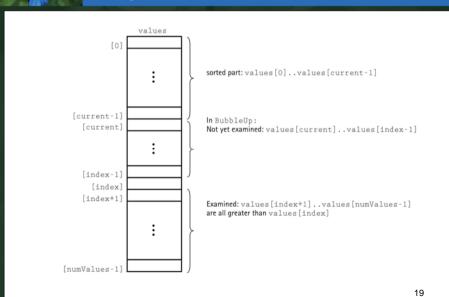

```
values [0] 36
[1] 24
[2] 10
[3] 6
[4] 12
```

Compares neighboring pairs of array elements, starting with the last array element, and swaps neighbors whenever they are not in correct order.

On each pass, this causes the smallest element to "bubble up" to its correct place in the array.

18

## **Snapshot of BubbleSort**

## Code for BubbleSort

```
template < class ItemType >
void BubbleSort(ItemType values[],
   int numValues)
{
   int current = 0;
   while (current < numValues - 1)
   {
      BubbleUp(values, current, numValues-1);
      current++;
   }
}</pre>
```

## Code for BubbleUp

```
template<class ItemType>
void BubbleUp(ItemType values[],
  int startIndex, int endIndex)
// Post: Adjacent pairs that are out of
     order have been switched between
     values[startIndex]..values[endIndex]
    beginning at values[endIndex].
  for (int index = endIndex;
    index > startIndex; index--)
    if (values[index] < values[index-1])</pre>
      Swap(values[index], values[index-1]);
```

**Observations on BubbleSort** 

This algorithm is always  $O(N^2)$ .

There can be a large number of intermediate swaps.

Can this algorithm be improved?

22

## **Insertion Sort**

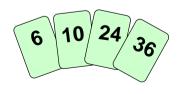

values [0]	36
[1]	24
[2]	10
[3]	6
[4]	12

One by one, each as yet unsorted array element is inserted into its proper place with respect to the already sorted elements.

On each pass, this causes the number of already sorted elements to increase by one.

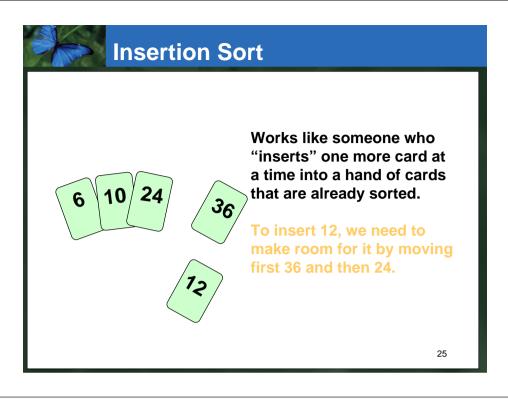

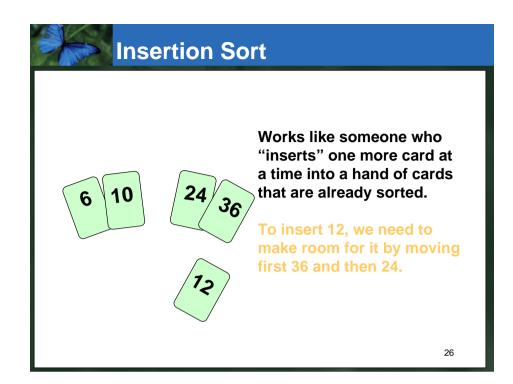

## **Insertion Sort**

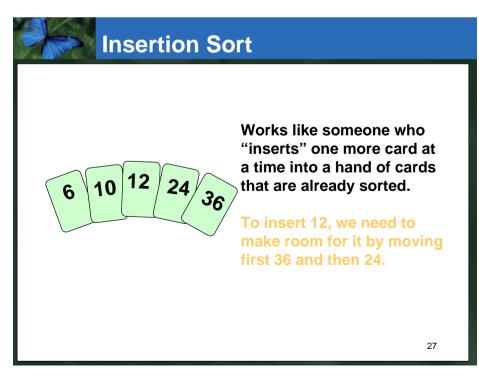

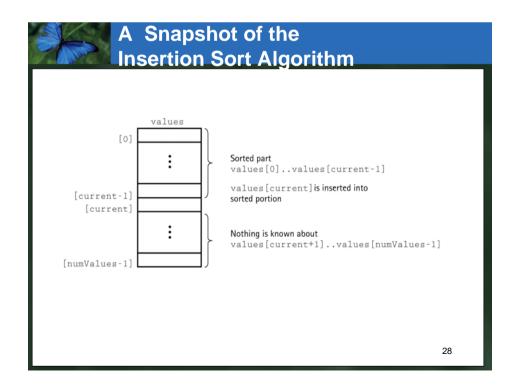

Works like someone who "inserts" one more card at a time into a hand of cards that are already sorted.

To insert 12, we need to make room for it by moving first 36 and then 24.

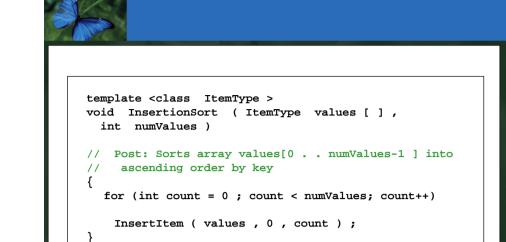

```
template <class ItemType >
void InsertItem ( ItemType values [ ] ,  int start ,
  int end )

// Post: Elements between values[start] and values

// [end] have been sorted into ascending order by key.

{
  bool finished = false ;
  int current = end ;
  bool moreToSearch = (current != start);

  while (moreToSearch && !finished )
  {
    if (values[current] < values[current - 1])
        {
        Swap(values[current], values[current - 1);
        current--;
        moreToSearch = ( current != start );
        }
        else
            finished = true ;
    }
}</pre>
```

30

## **Sorting Algorithms and Average Case Number of Comparisons**

## **Simple Sorts**

- Straight Selection Sort
- Bubble Sort
- Insertion Sort

## **More Complex Sorts**

- Quick Sort
- Merge Sort
- Heap Sort

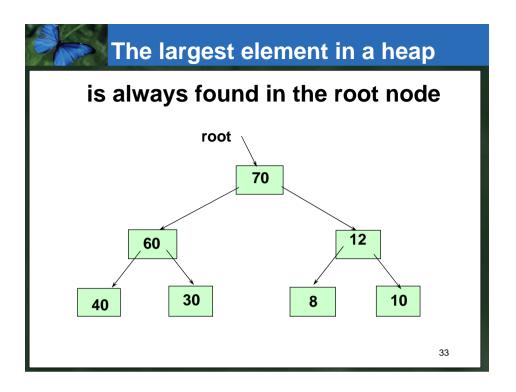

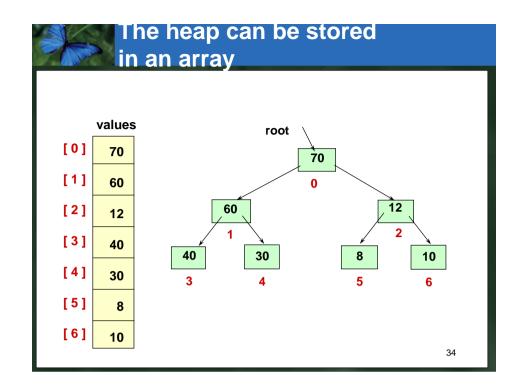

## Recall that ...

A heap is a binary tree that satisfies these special SHAPE and ORDER properties:

- ■Its shape must be a complete binary tree.
- For each node in the heap, the value stored in that node is greater than or equal to the value in each of its children.

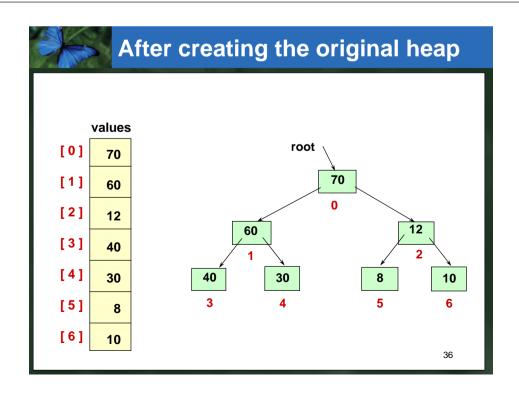

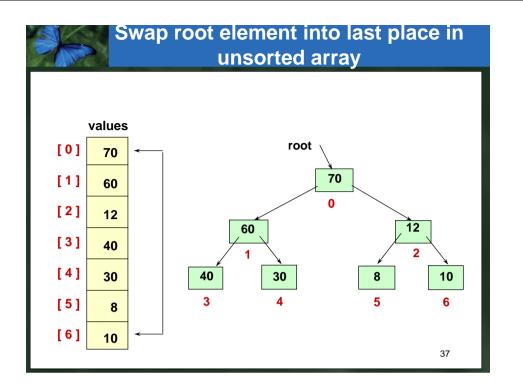

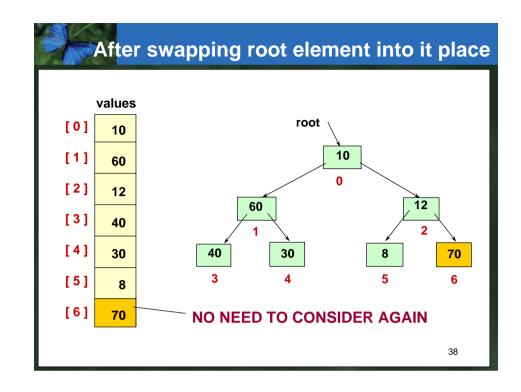

## **Heap Sort Approach**

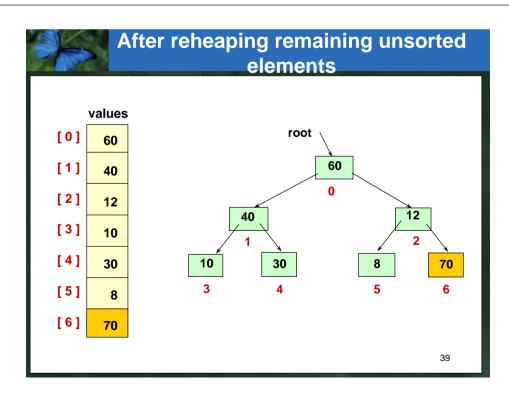

First, make the unsorted array into a heap by satisfying the order property. Then repeat the steps below until there are no more unsorted elements.

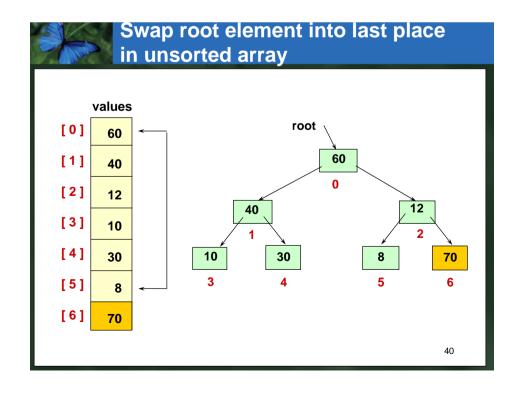

- Take the root (maximum) element off the heap by swapping it into its correct place in the array at the end of the unsorted elements.
- Reheap the remaining unsorted elements.
   (This puts the next-largest element into the root position).

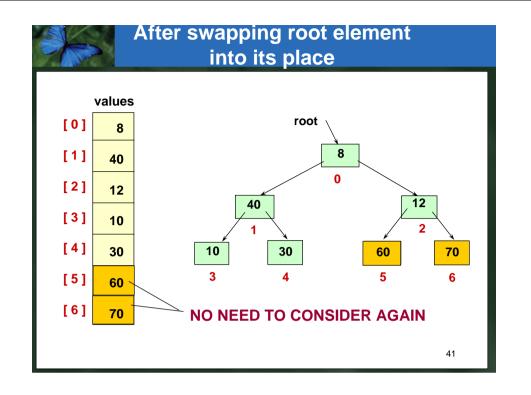

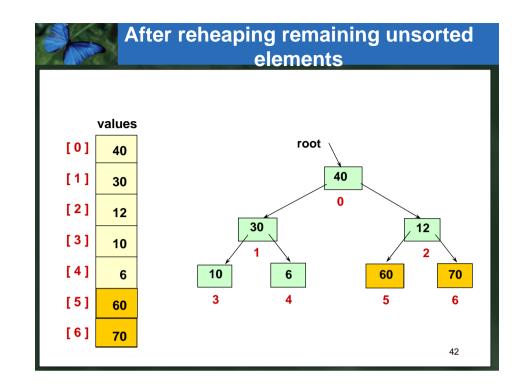

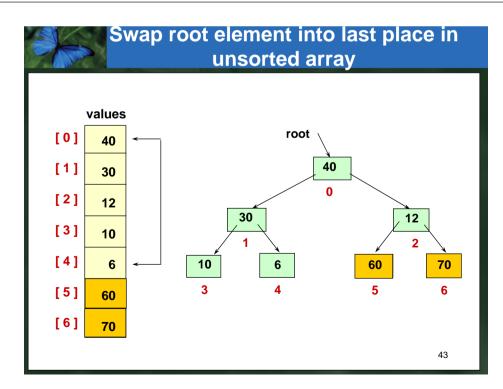

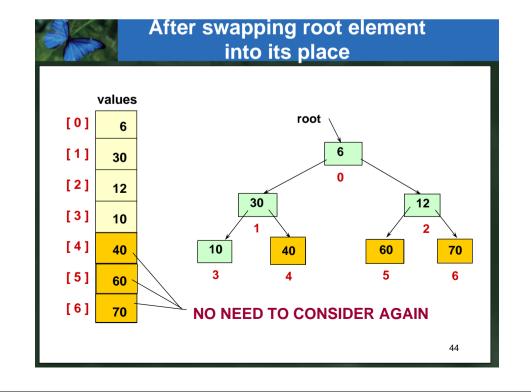

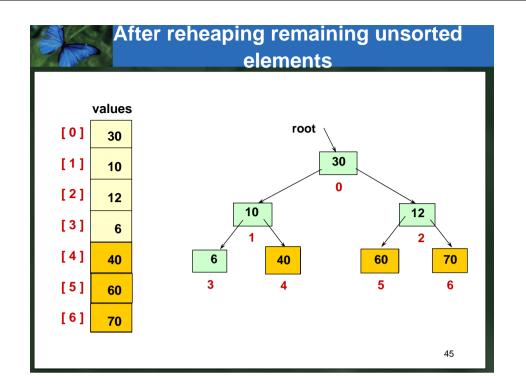

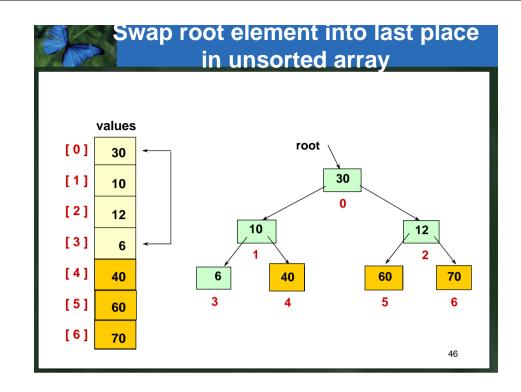

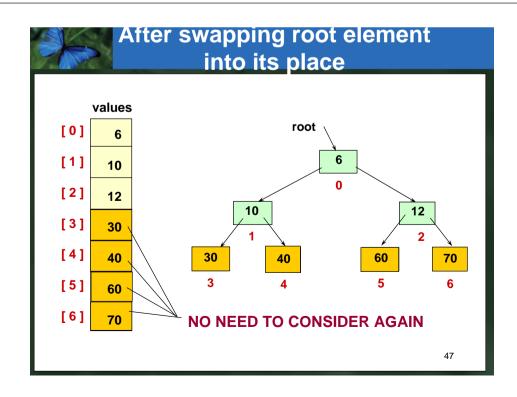

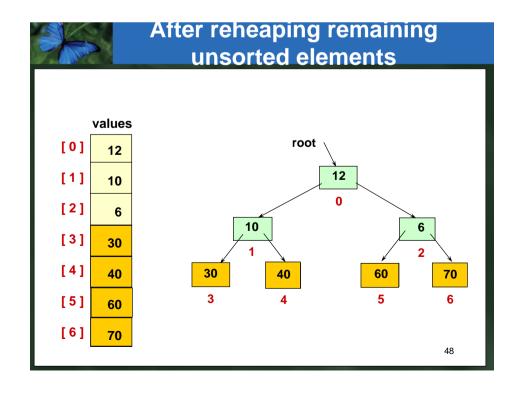

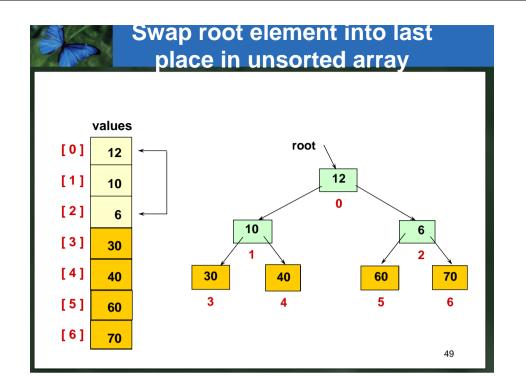

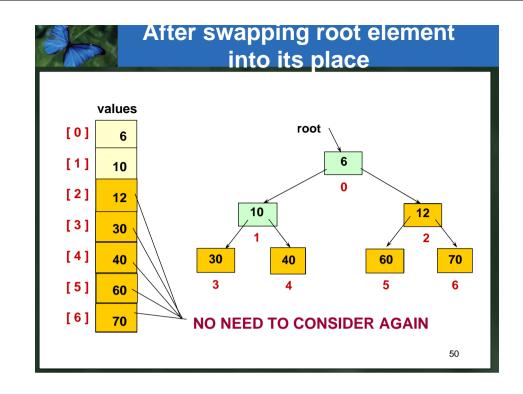

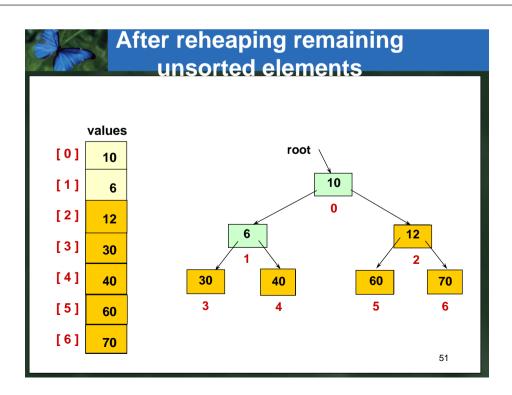

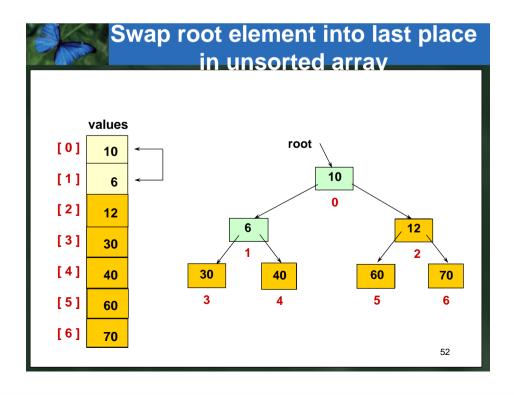

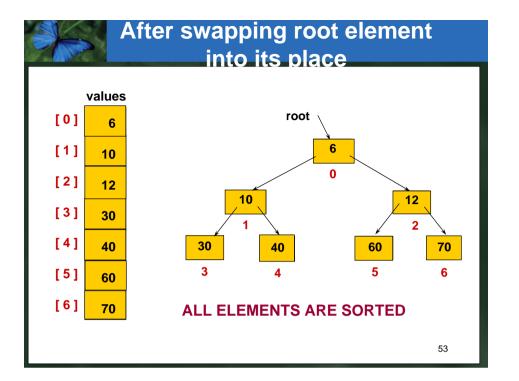

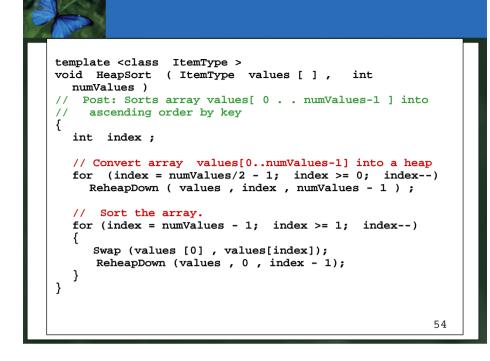

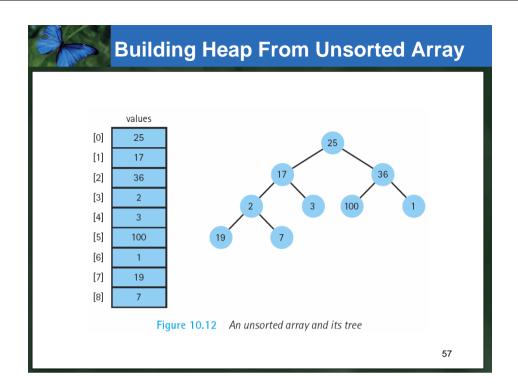

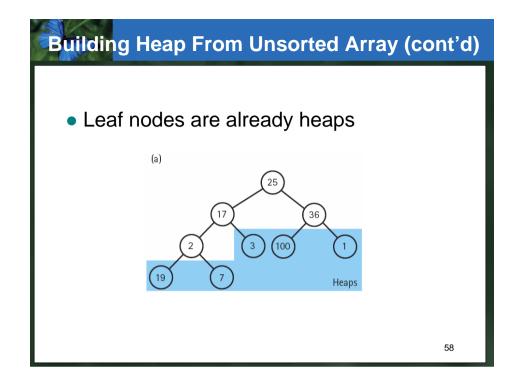

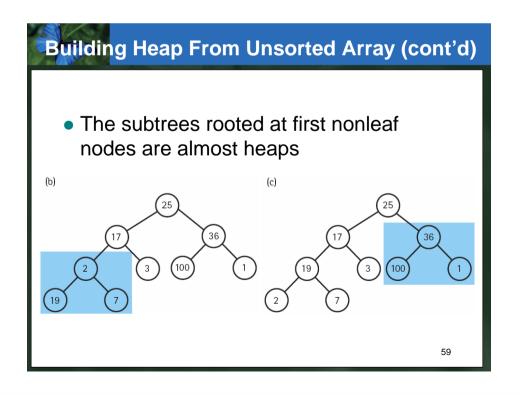

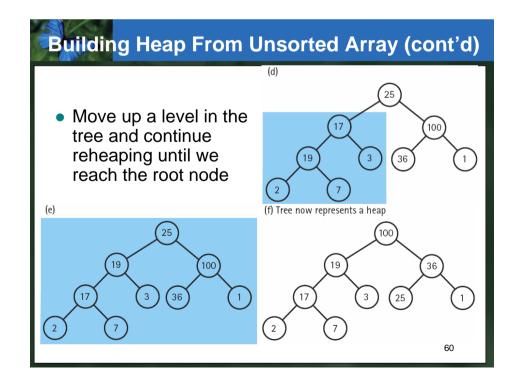

## template< class ItemType > void ReheapDown ( ItemType values [ ], int root, int bottom ) // Pre: root is the index of a node that may violate the heap order property // Post: Heap order property is restored between root and bottom { int maxChild; int rightChild; int leftChild; leftChild = root \* 2 + 1; rightChild = root \* 2 + 2;

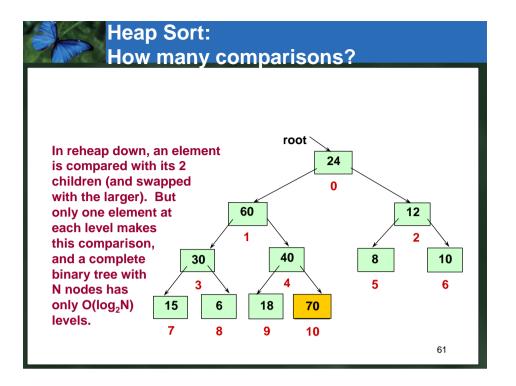

```
if (leftChild <= bottom)  // ReheapDown continued
{
  if (leftChild == bottom)
    maxChild = leftChild;
  else
  {
    if (values[leftChild] <= values [rightChild])
      maxChild = rightChild;
    else
      maxChild = leftChild;
  }
  if (values[root] < values[maxChild])
  {
      Swap (values[root], values[maxChild]);
      ReheapDown ( maxChild, bottom ;
    }
  }
}</pre>
```

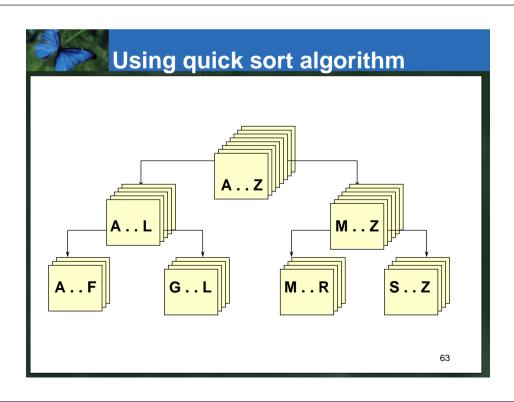

(N/2) \* O(log N) compares to create original heap

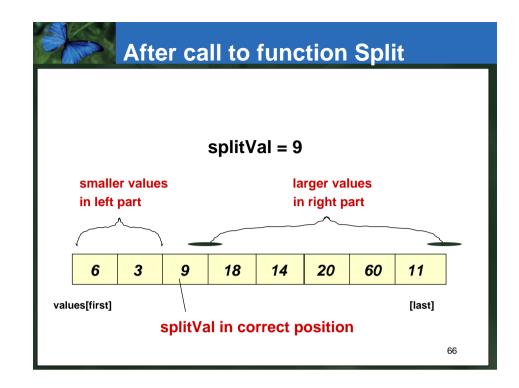

(N-1) \* O(log N) compares for the sorting loop

= O ( N \* log N) compares total

```
// Recursive quick sort algorithm
template <class ItemType >
void QuickSort ( ItemType values[ ] , int first ,
  int last )
// Pre: first <= last
   Post: Sorts array values[ first . . last ] into
   ascending order
  if (first < last)</pre>
                                    // general case
     int splitPoint;
      Split ( values, first, last, splitPoint );
      // values [first]..values[splitPoint - 1] <= splitVal</pre>
     // values [splitPoint] = splitVal
     // values [splitPoint + 1]..values[last] > splitVal
      QuickSort(values, first, splitPoint - 1);
      QuickSort(values, splitPoint + 1, last);
} ;
```

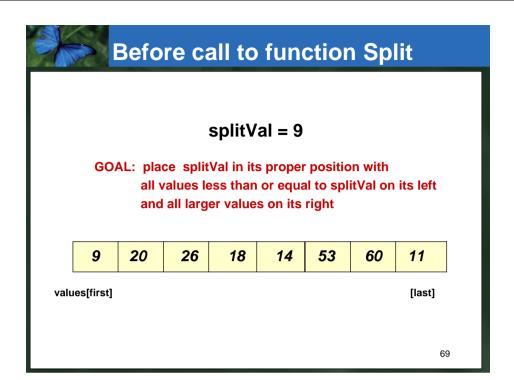

# N For first call, when each of N elements is compared to the split value 2 \* N/2 For the next pair of calls, when N/2 elements in each "half" of the original array are compared to their own split values. 4 \* N/4 For the four calls when N/4 elements in each "quarter" of original array are compared to their own split values. HOW MANY SPLITS CAN OCCUR?

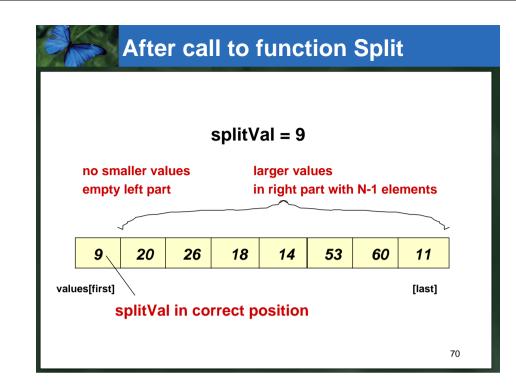

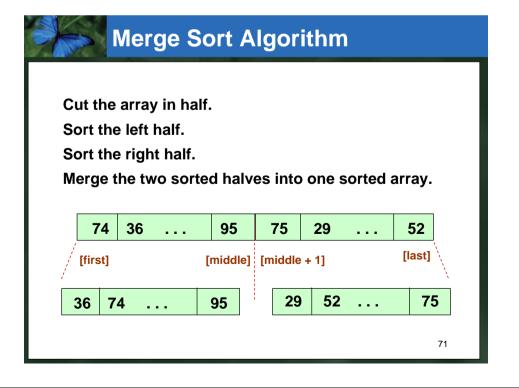

It depends on the order of the original array elements!

If each split divides the subarray approximately in half, there will be only  $\log_2 N$  splits, and QuickSort is  $O(N^*\log_2 N)$ .

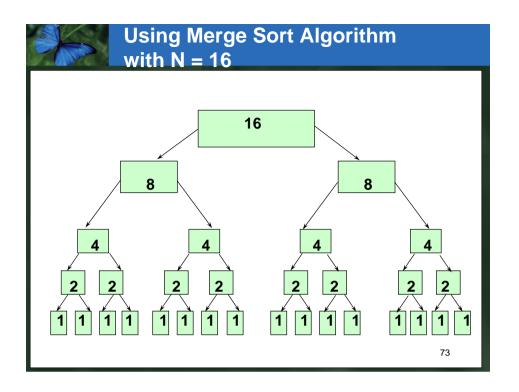

But, if the original array was sorted to begin with, the recursive calls will split up the array into parts of unequal length, with one part empty, and the other part containing all the rest of the array except for split value itself. In this case, there can be as many as N-1 splits, and QuickSort is O(N<sup>2</sup>).

```
// Recursive merge sort algorithm
template <class ItemType >
void MergeSort ( ItemType values[ ] , int first ,
  int last )
   Pre: first <= last
   Post: Array values[first..last] sorted into
      ascending order.
     ( first < last )
                                    // general case
      int middle = ( first + last ) / 2 ;
      MergeSort ( values, first, middle );
      MergeSort( values, middle + 1, last );
      // now merge two subarrays
      // values [ first . . . middle ] with
      // values [ middle + 1, . . . last ].
      Merge(values, first, middle, middle + 1, last);
```

## Merge Sort of N elements: How many comparisons?

The entire array can be subdivided into halves only log<sub>2</sub>N times.

Each time it is subdivided, function Merge is called to re-combine the halves. Function Merge uses a temporary array to store the merged elements. Merging is O(N) because it compares each element in the subarrays.

Copying elements back from the temporary array to the values array is also O(N).

MERGE SORT IS O(N\*log<sub>2</sub>N).

74

## **Comparison of Sorting Algorithms**

	Order of Magnitude					
Sort	Best Case	Average Case	Worst Case			
selectionSort	O(N2)	O(N <sup>2</sup> )	O(N2)			
bubbleSort	O(N2)	O(N <sup>2</sup> )	O(N <sup>2</sup> )			
shortBubble	O(N) (*)	O(N2)	O(N <sup>2</sup> )			
insertionSort	O(N) (*)	O(N <sup>2</sup> )	O(N <sup>2</sup> )			
mergeSort	$O(N\log_2 N)$	$O(N\log_2 N)$	$O(N\log_2 N)$			
quickSort	$O(N\log_2 N)$	$O(N\log_2 N)$	$og_2N$ ) $O(N^2)$ (depends on split			
heapSort	$O(N\log_2 N)$	$O(N\log_2 N)$	$O(N\log_2 N)$			

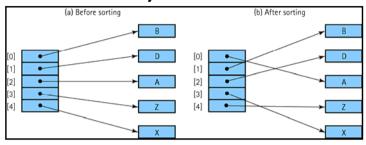

## **Testing**

- To thoroughly test our sorting methods we should vary the size of the array they are sorting
- Vary the original order of the array-test
  - Reverse order
  - Almost sorted
  - All identical elements

## **Sorting Objects**

 When sorting an array of objects we are manipulating references to the object, and not the objects themselves

77

## Stability

- Stable Sort: A sorting algorithm that preserves the order of duplicates
- Of the sorts that we have discussed in this book, only heapSort and quickSort are inherently unstable

78

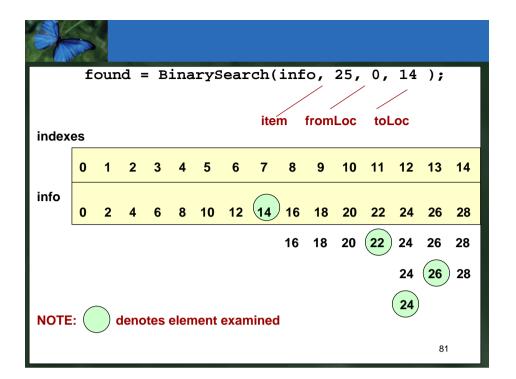

## Searching

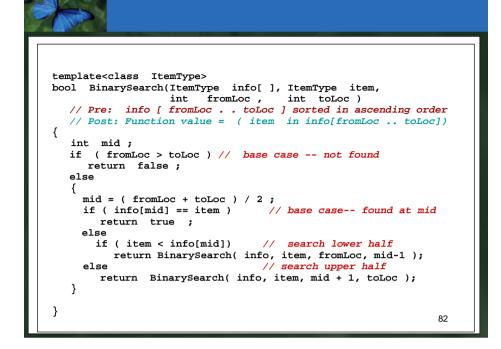

- Linear (or Sequential) Searching
  - Beginning with the first element in the list, we search for the desired element by examining each subsequent item's key
- High-Probability Ordering
  - Put the most-often-desired elements at the beginning of the list
  - Self-organizing or self-adjusting lists
- Key Ordering
  - Stop searching before the list is exhausted if the element does not exist

## Function BinarySearch( )

- BinarySearch takes sorted array info, and two subscripts, fromLoc and toLoc, and item as arguments. It returns false if item is not found in the elements info[fromLoc...toLoc]. Otherwise, it returns true.
- BinarySearch is  $O(log_2N)$ .

## Hashing

- is a means used to order and access elements in a list quickly -- the goal is O(1) time -- by using a function of the key value to identify its location in the list.
- The function of the key value is called a hash function.

FOR EXAMPLE...

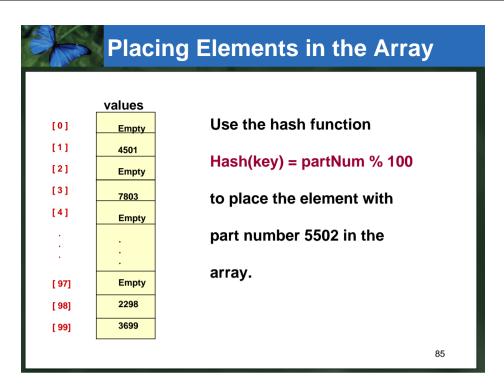

## Using a hash function

	values
[0]	Empty
[1]	4501
[2]	Empty
[3]	7803
[4]	Empty
· ·	
[ 97]	Empty
[ 98]	2298
[ 99]	3699

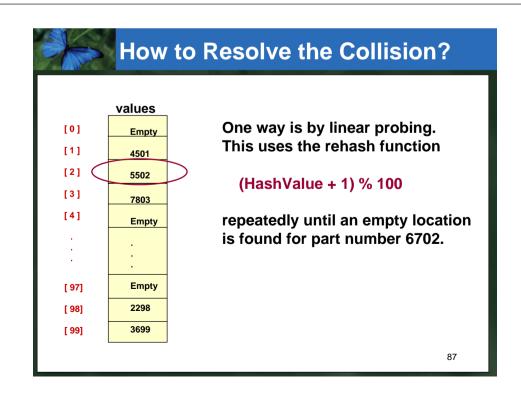

HandyParts company makes no more than 100 different parts. But the parts all have four digit numbers.

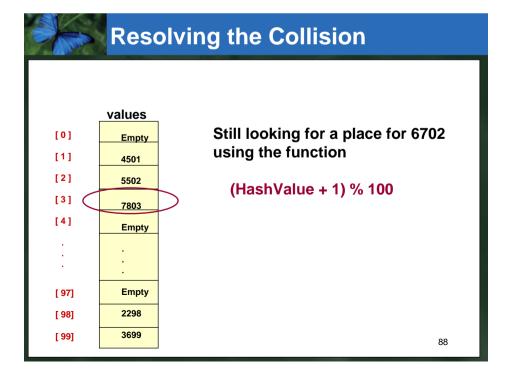

This hash function can be used to store and retrieve parts in an array.

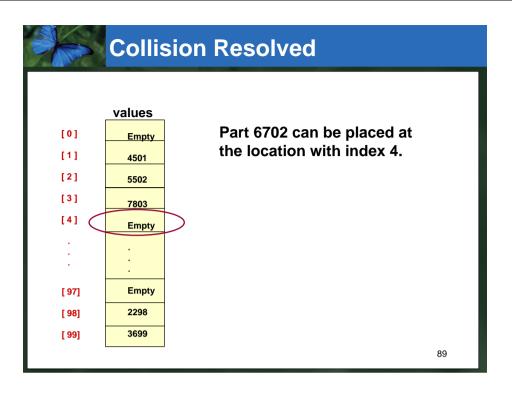

Hash(key) = partNum % 100

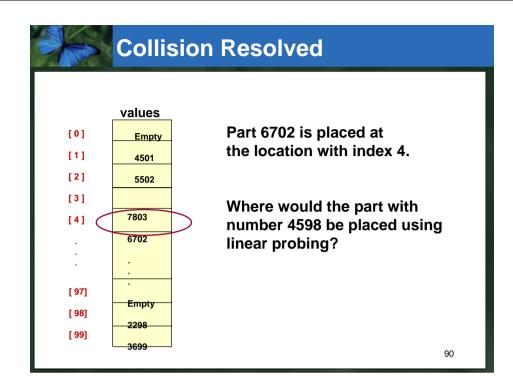

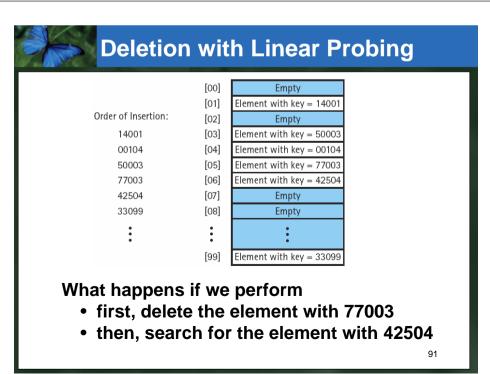

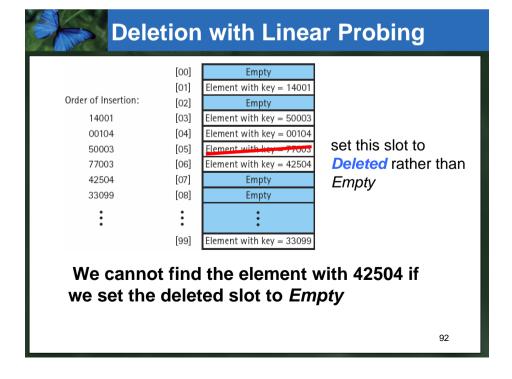

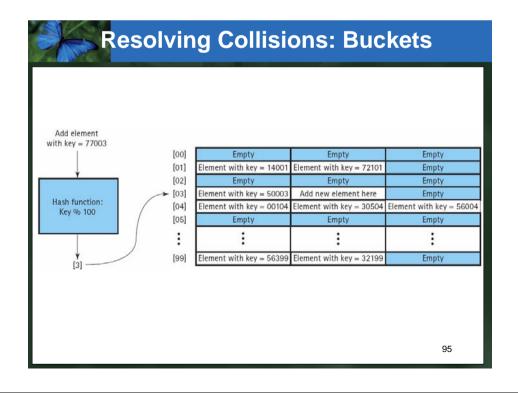

## **Resolving Collisions: Rehashing**

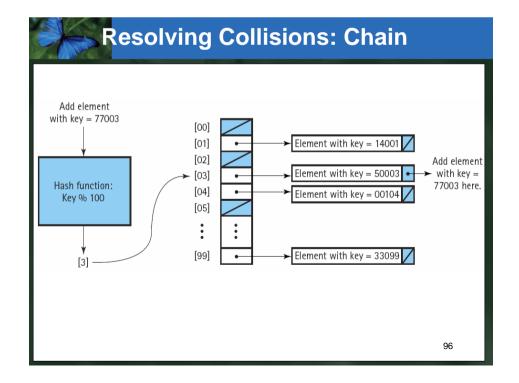

- Resolving a collision by computing a new hash location from a hash function that manipulates the original location rather than the element's key
- Linear probing
  - (HashValue + 1) % 100
  - (HashValue + constant) % array-size
- quadratic probing
  - (HashValue ± l²) % array-size
- random probing
  - (HashValue + random-number) % array-size

93

## Resolving Collisions: Buckets and Chaining

- The main idea is to allow multiple element keys to hash to the same location
- Bucket A collection of elements associated with a particular hash location
- Chain A linked list of elements that share the same hash location

## **Choosing a Good Hash Functions**

- Two ways to minimize collisions are
  - Increase the range of the hash function Distribute elements as uniformly as possible throughout the hash table
- How to choose a good hash function
  - Utilize knowledge about statistical distribution of keys

97

- Select appropriate hash functions
  - division method
  - sum of characters
  - folding

- ...

Is *not* a comparison sort

**Radix Sort** 

Uses a radix-length array of queues of records

Makes use of the values in digit positions in the keys to select the queue into which a record must be enqueued

98
